

7 December 2017

Announcement

- *Long Island mining strategy to go ahead, further extending mine life*
- *Additional ball mill approved to lift plant throughput and gold recovery*
- *2.1 million ounces of gold production added to the Tropicana business plan*
- *Ore Reserve increased to 4.08 Moz (100% project)*
- *Underground mining potential enhanced by encouraging Boston Shaker drilling results*

Tropicana partners AngloGold Ashanti and Independence Group commit to Long Island

(Perth) -- AngloGold Ashanti Australia Ltd (AGAA) is pleased to announce that the partners in the Tropicana Joint Venture have approved Phase One of the Long Island strategy, increasing production from the mine in the medium term and extending mine life.

Long Island has been driven by developing a more cost-effective way to mine waste. It involves using a strip-mining approach that minimizes waste haulage distances by using in-pit backfill, rather than trucking the material long distances to surface waste dumps.

The Tropicana Gold Mine, located 330 kilometers east-northeast of Kalgoorlie in Western Australia, is owned by AGAA (70% and manager) and Independence Group NL (30%).

Phase One of Long Island comprises mining of the Havana South pit and a cutback of the Boston Shaker pit, which utilizes the completed Tropicana pit as the first backfill location.

The full Long Island strategy adds 2.1 million ounces to Tropicana's business plan, extending mine life by approximately seven years to 2027. The project value has been enhanced by the decision to install a 6MW ball mill in the processing plant, enabling throughput to be matched to the increased mining rate and improving gold recovery by 3% to approximately 92%.

Grade streaming, which prioritizes the processing of higher-grade ore and stockpiling lower-grade material for processing at a later date, has resumed at Tropicana and will continue through 2018 and 2019. Gold production (100%) is forecast to be between 478,000oz and 492,000oz next year and between 530,000oz–548,000oz in 2019.

“This project is in line with our approach of developing cost-effective brownfield projects with attractive payback periods that extend life and improve margins,” said Michael Erickson, AngloGold Ashanti's Senior Vice President Australia. “The project validates the innovative ideas developed by our site team

and technical specialists, and also gives us an excellent base from which we can investigate adding additional value through underground mining opportunities and regional exploration.”

Gold production over Tropicana’s remaining life of mine is now forecast to be about 4Moz. This does not include potential future underground production from mineralization at the Boston Shaker ore body, which remains open at depth. A pre-feasibility study on underground mining will be commissioned in 2018.

The Long Island strategy is underpinned by continued exploration success, evidenced by another increase in the Ore Reserve to 66.59 Mt grading 1.91 g/t for a total of 4.08 Moz. This represents an increase of 280,000oz over the past year, even after depletion of about 550,000oz is taken into account.

Including gold produced to date, Tropicana has delivered a 72% increase in Ore Reserves since the Tropicana project was approved in November 2010. (*Full Ore Reserve and Mineral Resource information can be found in Appendix One.*)

Long Island strategy

As part of the cost-effective strip mining approach, waste haulage distances are reduced by using in-pit backfill. After initially considering mining a starter pit at Havana South to act as a void for waste in the proposed pit cutbacks, it became apparent from drilling that because there was limited upside beneath the Tropicana pit, it would provide significant value as a backfill location.

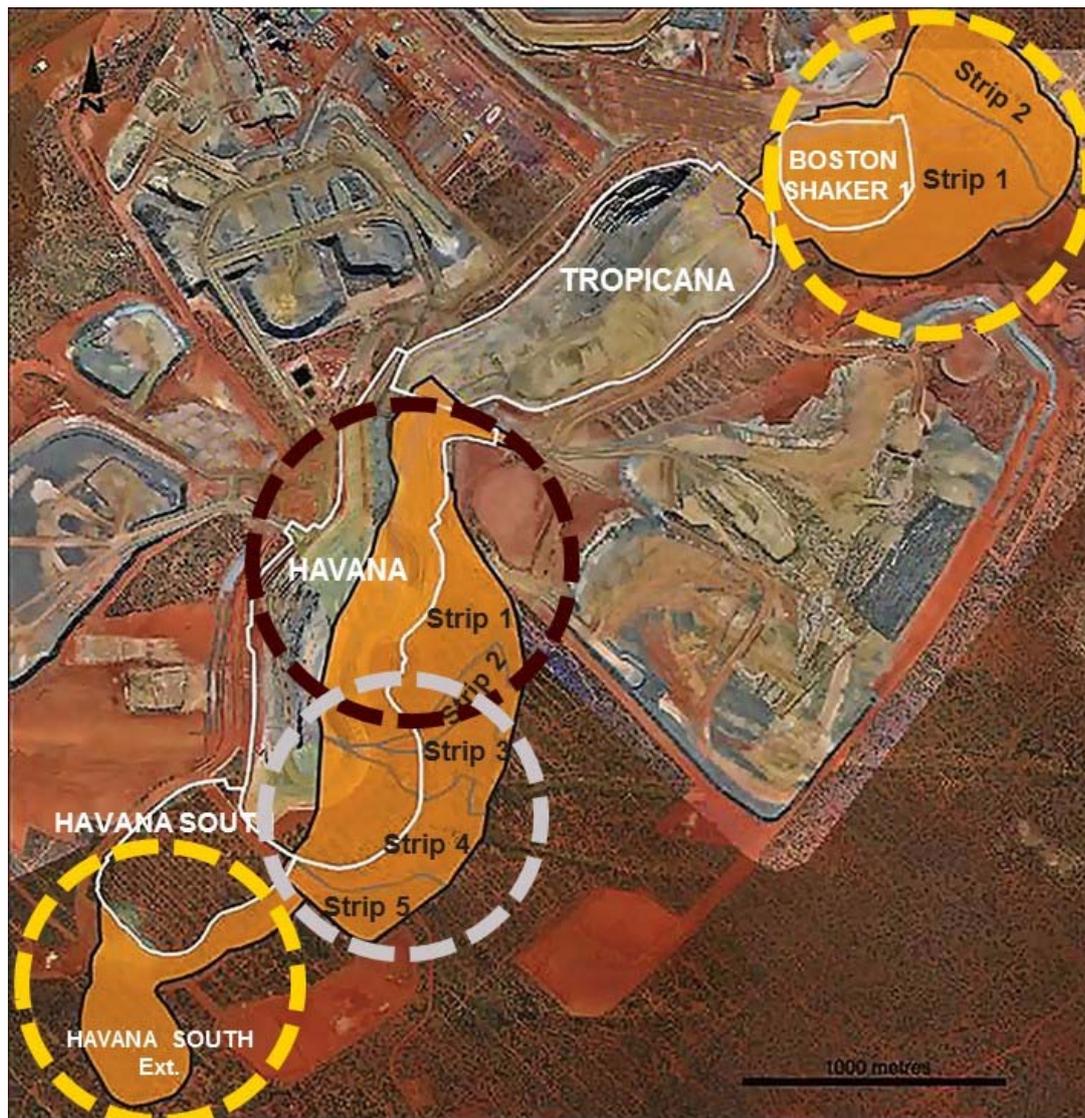

As previously reported, the Long Island concept provides optionality and flexibility, with eight mining stages and three decision points (see *Figure 1*) giving the opportunity to adjust to changing economic conditions. If all three phases are implemented mine life will be extended to 2027.

Mining rates at Tropicana have been successfully increased over the past year to more than 90 Mtpa with the addition last year of a 600 tonne face shovel, de-risking the increase to the Long Island mining rate of between 95-107 Mtpa. The mining rate will peak at 107 Mtpa in 2019 and continue at that rate for about four years until the bulk of the Havana pit is mined.

To achieve the additional material movement increase, a second 600t shovel with up to five additional Caterpillar 793 trucks and supporting ancillary equipment, will be added to the fleet. The capital expenditure related to Long Island will be approximately A\$18 million, primarily for expansion to the accommodation camp and heavy vehicle workshop infrastructure.

The additional fleet will be provided by Macmahon Holdings as part of the mining contract at the site.

Productivity improvements through AGA’s Operational Excellence programme have resulted in a reduction in mining costs at Tropicana over the past two years to A\$3.07/t using conventional mining methods. It is anticipated that ongoing mining efficiencies will further reduce mining costs by 5-10% during Phase One.

**BP2018
Commitment**

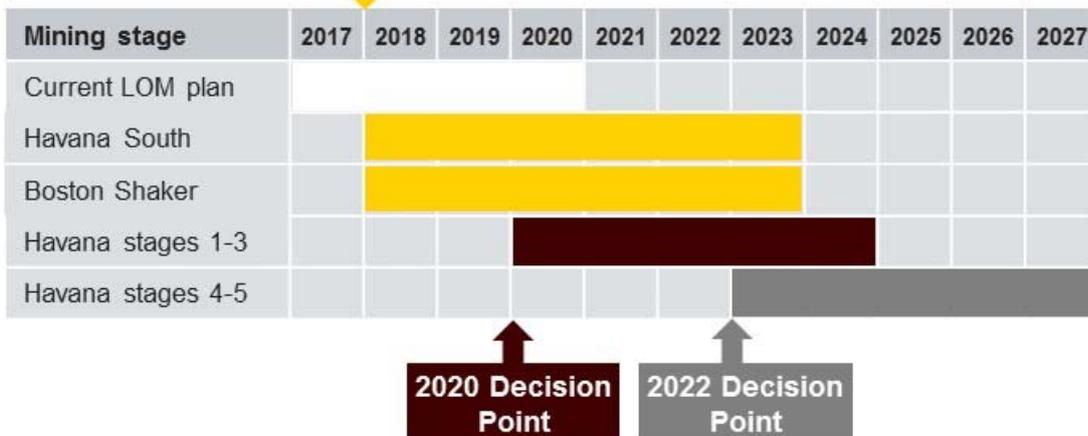

Figure 1: Plan view of mining locations – eight stages and three decision points Boston Shaker drilling and underground PFS

Diamond drilling beneath the Boston Shaker pit in the second half of 2017 has returned encouraging intercepts including: 18m at 6.58 g/t from 587m depth (BSD087W1), 37m at 6.49 g/t from 509m (BSD088); and 20m at 5.82 g/t from 609m (BSD089AW2). See Figure 2 and Figure 3 and detailed table of intercepts in appendices.

Step out holes BSD090 and BSD091A have confirmed mineralisation up to 1,000m down dip of the Long island pit design.

Evaluation of open pit grade control drilling shows strong grade continuity in the Boston Shaker southern ore shoot. This, combined with the thick zones of high-grade mineralisation identified in recent exploration drilling, suggests the Boston Shaker ore zones will be amenable to underground mining.

A Pre-Feasibility Study will be carried out in 2018 to investigate potential for underground mining at Boston Shaker with the aim of defining an underground Ore Reserve by the end of the calendar year. The PFS will include infill drilling and mining studies.

Successful development of an underground mine at Boston Shaker has the potential to contribute high grade ore to the processing plant from 2021 onwards.

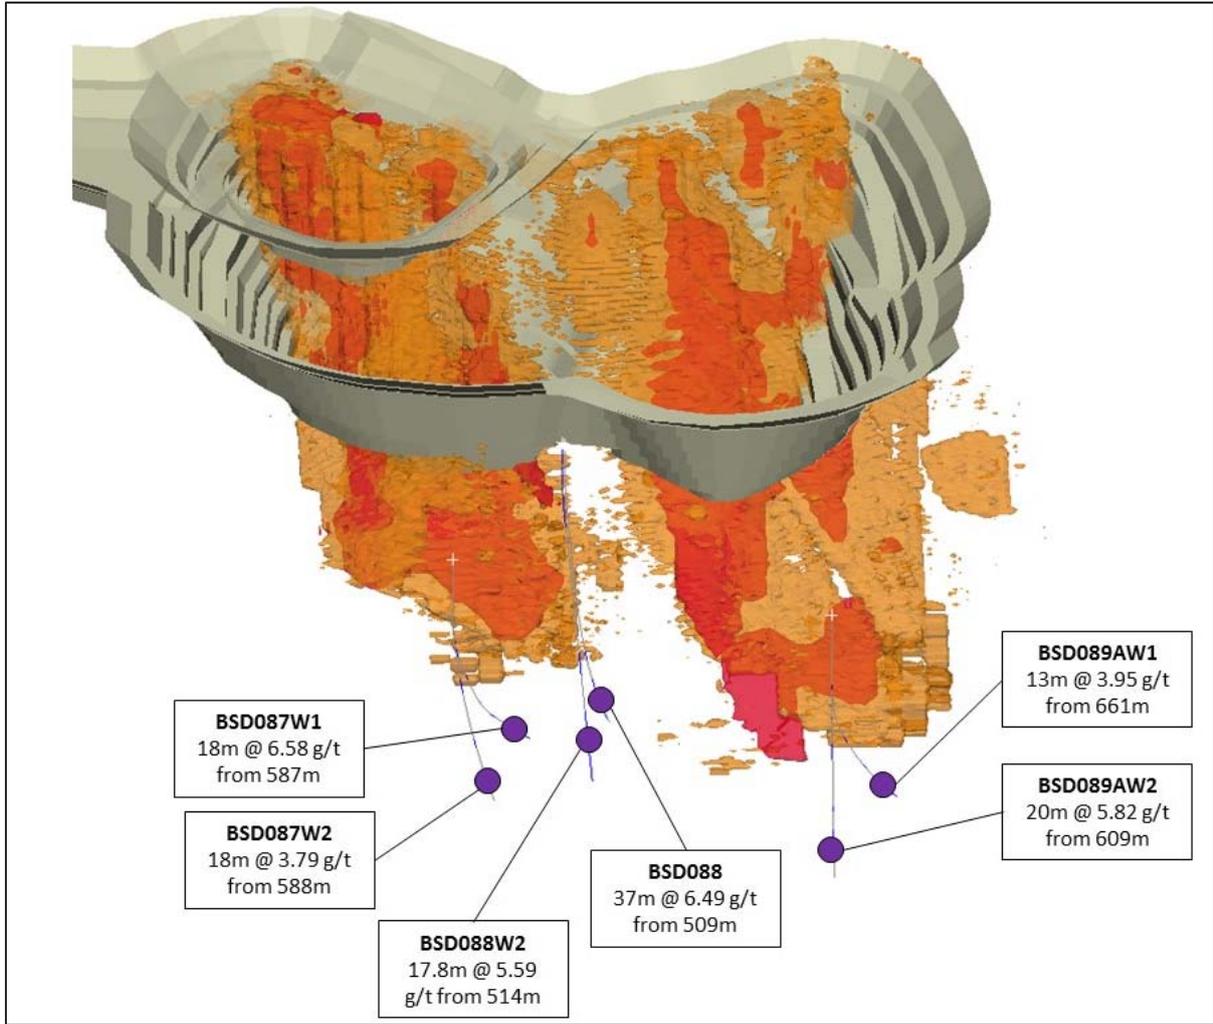

Figure 2: Boston Shaker recent drill intercepts

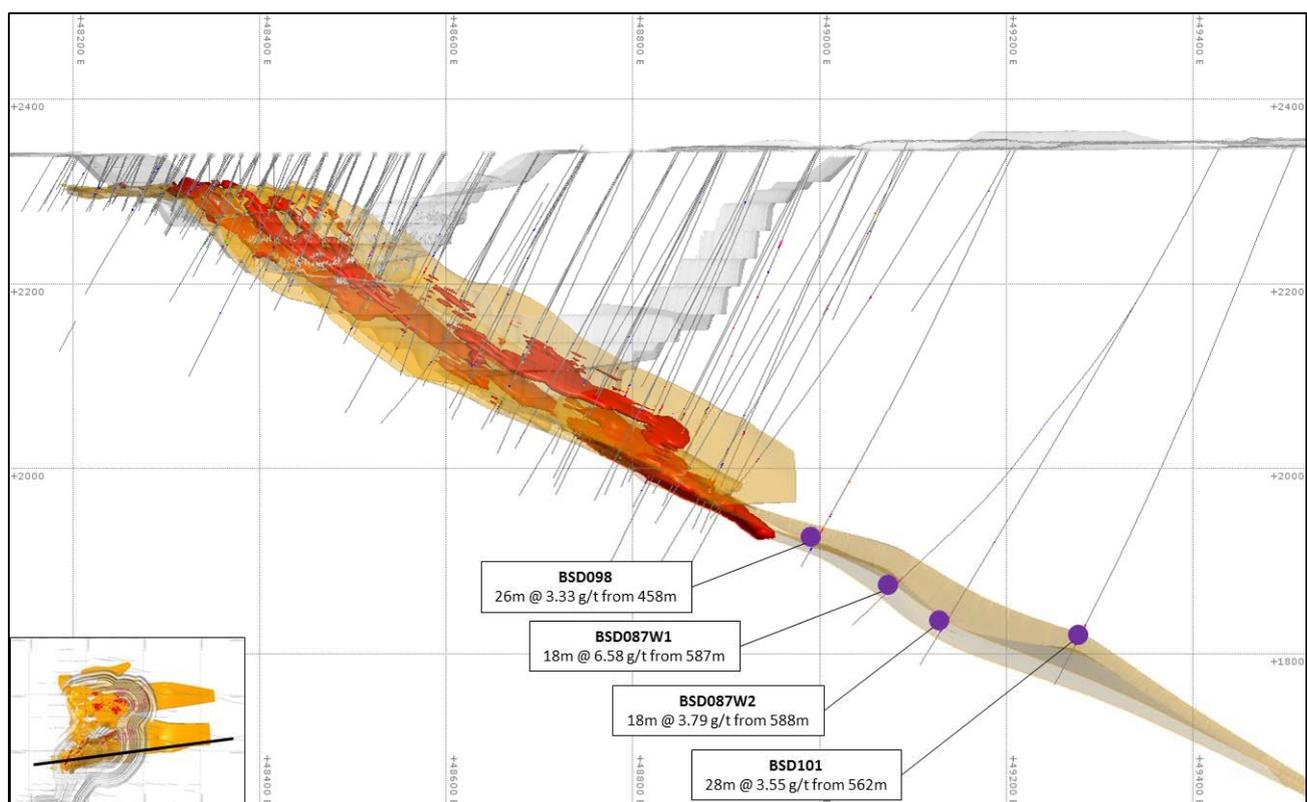

Figure 3: Boston Shaker cross-section.

Approval of additional ball mill

The installation of a second ball mill in the Tropicana processing plant grinding circuit has been approved. The 6MW ball mill will enable the annual throughput rate to be lifted to approximately 8.1Mtpa and through a reduction in grind size, baseline metallurgical recovery will be improved by up to 3%, to approximately 92%.

The increased throughput will efficiently match processing capacity to the Long Island mining rate, and effectively bring forward gold production delivering the best production profile for the operation. The improved recovery rate will add approximately 120,000 oz to recovered gold over the life of mine.

Total capital expenditure is anticipated to be A\$28 million (100%) including equipment, construction cost and spares, and the new mill is scheduled to be commissioned in Q4 2018. The site has adequate power generation capacity to cater for the additional mill and no further infrastructure is required.

Based on mill throughput of 8.1 Mtpa and a recovery improvement of 2.7% in the first year the payback period will be less than a year.

The additional ball mill follows a range of expansion and optimization projects that have lifted the throughput rate at commissioning from a nameplate 5.8 Mtpa to approximately 7.6 Mtpa by the end of 2017.

A fines pulping circuit was commissioned in November this year, further improving efficiency by minimizing downtime during maintenance shutdowns.

Regional Exploration

Regional exploration at Tropicana in 2017 has been guided by new thinking and work completed through 2016.

Palinspastic reconstruction and a geological review have provided an updated understanding and revised interpretation of the regional geology and prospectivity in the belt. The evolution of this work continues, with inputs from current exploration drilling and further specialist and academic work.

In 2017, a balanced strategy was adopted, comprising resource development at Tropicana, and early-to-advanced stage exploration regionally.

Advanced exploration continued to evaluate existing prospects (Madras, Voodoo Chile, Angel Eyes, Springbok) and to advance the New Zebra anomaly identified through aircore drilling in late 2016. Early stage aircore drilling was carried out at Chocalatini, Iceburg, Caprioska and Watchtower.

Following exceptional results at Boston Shaker in 2017, priority was given to resource development drilling to evaluate underground potential. This focus will continue in 2018 along with regional exploration to test new targets identified as a result of the palinspastic reconstruction.

Ore Reserve and Mineral Resource update

As part of the Long Island study a total of 193,554 metres of drilling was carried out between 2015 and 2017 to test the down-dip extent of the Tropicana Mineral Resource at Havana South, Tropicana and Boston Shaker.

This delivered an increased Mineral Resource which formed the foundation of the Long Island study.

The Ore Reserve (as at 31 December 2017) has increased by 830,000 oz, excluding depletion, over the past 12 months.

Table 1. Tropicana Ore Reserves (100% Project) as at 31 December 2017*

Area	Reserves Category	Dec-16			Dec-17			Change		
		Mt	g/t	Moz	Mt	g/t	Moz	Mt	g/t	Moz
Open Pit	Proved	15.7	1.48	0.75	17.4	1.29	0.72	1.7	-0.18	-0.02
	Probable	44.4	2.14	3.05	49.2	2.12	3.36	4.8	-0.02	0.30
	Total	60.1	1.97	3.80	66.6	1.91	4.08	6.5	-0.06	0.28

*Including depletion of 7.15 Mt at 2.38 g/t for 0.55 Moz.

Notes:

1. The Proven and Probable Ore Reserve are reported above economic break-even gold cut-off grades for each material type at a gold price of A\$1,491/oz (US\$1,100/oz).
2. The Ore Reserve estimate is based on depletion through to the 31 December 2017, using the Resource model from June 2017.
3. The cut-off grades reported were 0.6g/t Au for oxide material and 0.7g/t Au for transitional and fresh.
4. All figures are rounded to reflect appropriate levels of confidence. Apparent differences may occur due to rounding.
5. Mineral Resources are inclusive of Ore Reserves.
6. All Mineral Resources are compiled in accordance with the 2012 JORC Code.
7. JORC Code (2012) Table 1 Parameters are contained within Appendix B of this ASX release

Notes:

1. The Open Pit Mineral Resource is reported above a marginal (break-even) cut-off grade of 0.3g/t Au cut-off for oxide material, and a 0.4g/t Au cut-off for transitional and fresh material. Cut-off grades for Mineral Resources have been based on an A\$1,817/oz (US\$1,400/oz) gold price.
2. The Open Pit Mineral Resource is reported within a combination of pit designs and optimisation shells, reflecting the current Long Island mining strategy including; a) Havana South is reported within a A\$1,817/oz (US\$1,400/oz) gold price optimised shell, at Long Island study costs; b) Havana is reported within a pit design, based on Long Island Study costs at an A\$1,370/oz (US\$1,055/oz) gold price optimised shell; c) Tropicana is reported within the current life of mine design, and; d) Boston Shaker is reported within current life of mine design based on an A\$1,350 (US\$1,040/oz) gold price and Long Island Study costs.
3. All figures are rounded to reflect appropriate levels of confidence. Apparent differences may occur due to rounding.
4. Mineral Resources are inclusive of Ore Reserves.
5. All Mineral Resources are compiled in accordance with the 2012 JORC Code.
6. JORC Code (2012) Table 1 Parameters are contained within Appendix B of this ASX release.

JORC Code Competent Persons Statements

The information in this report that relates to Exploration Results is based on information compiled by Mr. Damon Elder who is a full-time employee of AngloGold Ashanti Australia Ltd and is a member of The Australasian Institute of Mining and Metallurgy. Mr Elder has sufficient experience which is relevant to the style of mineralisation and type of deposit under consideration and to the activity being undertaken to qualify as a Competent Person as defined in the 2012 Edition of the 'Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves'. Mr. Elder consents to the inclusion in the report of the matters based on his information in the form and context in which it appears.

The information that relates to the Tropicana Mineral Resources is based on, and fairly represents information and supporting documentation compiled by Mr Mark Kent, a full-time employee and security holder of AngloGold Ashanti Limited, who is a member of The Australasian Institute of Mining and Metallurgy. Mr Kent has sufficient experience relevant to the type and style of mineral deposits under consideration, and to the activity which has been undertaken, to qualify as a Competent Person as defined in the 2012 edition of the JORC Code. Mr Kent consented to the inclusion in this report of the Tropicana Mineral Resource estimate, based on the information in the form and context in which it appears.

The information that relates to the Tropicana Ore Reserves is based on, and fairly represents information and supporting documentation compiled by Mr Leonardo Vilela Couto, a full-time employee and security holder of AngloGold Ashanti Limited, who is a member of The Australasian Institute of Mining and Metallurgy. Mr Vilela Couto has sufficient experience relevant to the type and style of mineral deposit under consideration, and to the activity which has been undertaken, to qualify as a Competent Person as defined in the 2012 edition of the JORC Code. Mr Vilela Couto consented to the inclusion in this report of the Tropicana Ore Reserve estimate, based on the information, in the form and context in which it appears.

Certain statements contained in this document, other than statements of historical fact, including, without limitation, those concerning the economic outlook for the gold mining industry, expectations regarding gold prices, production, cash costs, all-in sustaining costs, all-in costs, cost savings and other operating results, productivity improvements, growth prospects and outlook of AngloGold Ashanti's operations, individually or in the aggregate, including the achievement of project milestones, commencement and completion of commercial operations of certain of AngloGold Ashanti's exploration and production projects and the completion of acquisitions, dispositions or joint venture transactions, AngloGold Ashanti's liquidity and capital resources and capital expenditures and the outcome and consequence of any potential or pending litigation or regulatory proceedings or environmental health and safety issues, are forward-looking statements regarding AngloGold Ashanti's operations, economic performance and financial condition.

These forward-looking statements or forecasts involve known and unknown risks, uncertainties and other factors that may cause AngloGold Ashanti's actual results, performance or achievements to differ materially from the anticipated results, performance or achievements expressed or implied in these forward-looking statements. Although AngloGold Ashanti believes that the expectations reflected in such forward-looking statements and forecasts are reasonable, no assurance can be given that such expectations will prove to have been correct. Accordingly, results could differ materially from those set out in the forward-looking statements as a result of, among other factors, changes in economic, social and political and market conditions, the success of business and operating initiatives, changes in the regulatory environment and other government actions, including environmental approvals, fluctuations in gold prices and exchange rates, the outcome of pending or future litigation proceedings, and business and operational risk management.

For a discussion of such risk factors, refer to AngloGold Ashanti's annual report on Form 20-F for the year ended 31 December 2016, which was filed with the United States Securities and Exchange Commission ("SEC"). These factors are not necessarily all of the important factors that could cause AngloGold Ashanti's actual results to differ materially from those expressed in any forward-looking statements. Other unknown or unpredictable factors could also have material adverse effects on future results. Consequently, readers are cautioned not to place undue reliance on forward-looking statements. AngloGold Ashanti undertakes no obligation to update publicly or release any revisions to these forward-looking statements to reflect events or circumstances after the date hereof or to reflect the occurrence of unanticipated events, except to the extent required by applicable law. All subsequent written or oral forward-looking statements attributable to AngloGold Ashanti or any person acting on its behalf are qualified by the cautionary statements herein.

The financial information contained in this news release has not been reviewed or reported on by the Company's external auditors.

This communication may contain certain "Non-GAAP" financial measures. AngloGold Ashanti utilises certain Non-GAAP performance measures and ratios in managing its business. Non-GAAP financial measures should be viewed in addition to, and not as an alternative for, the reported operating results or cash flow from operations or any other measures of performance prepared in accordance with IFRS. In addition, the presentation of these measures may not be comparable to similarly titled measures other companies may use. Intercepts calculated based on minimum intercept 2m @ 0.5 g/t, lower cut-off grade 0.5 g/t, maximum consecutive waste 2m, minimum intercept grade 1 g/t, calculation based on downhole length, true thickness/width not stated or calculated.

APPENDIX B

Tropicana Gold Mine Mineral Resource and Ore Reserve as at 31 December 2017

JORC Code, 2012 Edition – Table 1

Section 1 Sampling Techniques and Data

Criteria	Commentary
Sampling techniques	<ul style="list-style-type: none"> - AngloGold Ashanti Australia (AngloGold) has used drilling and sub-sampling of the cuttings or cores as the data basis for the Mineral Resource estimates of the Tropicana deposit. Details are given in the following subsection. - Drill hole spacing ranges from 25m×25m grids to 100m×100m grids, with most of the drilling of the Open Pit Mineral Resources on a 50m×50m spacing with 25m×25m testing the starter pits of the Tropicana and Havana initial pits, and the southern end of the Boston Shaker deposit. - A 100m×100m area of Havana was drilled out on a 10m×10m grid to validate the resource model and optimise the grade control sample spacing. - The Underground Mineral Resource down-plunge extensions of Havana Deeps is tested using a 100m×100m grid. Deep +800m deep step-out holes have been drilled on nominal ≈200m×100m to test the high-grade mineralisation of Havana Deeps. - All holes are drilled plunging towards the west to intersect the east dipping mineralised zones
Drilling techniques	<ul style="list-style-type: none"> - Reverse circulation (RC) percussion drilling using face-sampling bits (5 ¼ inch or 133 mm diameter) has been used to collect samples from the shallower (up-dip) part of the deposits with a nominal maximum RC depth of 150m. - Diamond core drilling has been used for deeper holes, with diamond tails drilled from RC pre-collars. To control the deviation of deep DD holes drilled since 2011, many of these holes were drilled from short ≈ 60m RC pre-collars or using 63.5mm (HQ) diameter core from surface. - Diamond core drilling for Mineral Resource definition is predominantly 47.6mm (NQ) diameter core, with a lesser number of holes drilled for collection of metallurgical and/or geotechnical data using 63.5mm (HQ2, HQ3) or 85mm (PQ) core diameters. - In fresh rock, cores are oriented wherever possible for collection of structural data. Prior to 2009, core orientations are made using the EzyMark tool with the Reflex Ace Tool replacing the system in later drilling programmes.

Criteria	Commentary
Drill sample recovery	<ul style="list-style-type: none"> - RC recovery <ul style="list-style-type: none"> o Prior to 2008 semi-quantitative assessment was made regarding RC sample recovery with recovery visually estimated as 25%, 50%, 75% of 100% of the expected mass volume of a 1m drilling interval. o Since 2008, AngloGold has implemented quantitative measure on every 25th interval where the masses of the sample splits are recorded and compared to the theoretical mass of the sampling interval for the rock type being drilled. o AngloGold found that overall recovery in the regolith was >80% and total recovery in fresh rock. - DD Recovery <ul style="list-style-type: none"> o DD recovery has been measured as percentage of the total length of core recovered compared to the drill interval. o Core recovery is consistently high in fresh rock with minor losses occurring in heavily fractured ground or for DD drilling in the regolith. - The main methods to maximise recovery have been recovery monitoring as described above and diamond core drilling below \approx 150m depth. - No relationships have been noted between sample recovery and grade and sample biases that may have occurred due to the preferential loss or gain of fine or coarse material are considered unlikely.
Logging	<ul style="list-style-type: none"> - RC cuttings and DD cores have been logged recording geological and geotechnical characteristics with reference to AngloGold's logging standard library, to levels of detail that support Mineral Resource estimation, Ore Reserve estimation and metallurgical studies. - Qualitative logging includes codes for lithology, regolith, and mineralisation for both RC and DD, with sample quality data recorded for RC such as moisture, recovery, and sub-sampling methods. - DD cores are photographed, qualitatively structurally logged with reference to orientation measurements where available. - Geotechnical quantitative logging includes QSI, RQD, and matrix and fracture characterisation. - The total lengths of all drill holes have been logged.
Sub-sampling techniques and sample preparation	<ul style="list-style-type: none"> - RC – Primary splitting <ul style="list-style-type: none"> o Prior to 2007 RC samples were collected from the cyclone stream using a tiered riffle splitter. From 2007 a static cone splitter was introduced and replaced riffle splitters on all rigs. o The RC sampling interval is generally 1m but from 2016 2m intervals were introduced for RC pre-collars. o The splitters collected a \approx 12% split from the primary lot with two 12% splits collected – the first for laboratory submission and second as a reference or replicate. Most samples were collected dry with <2% of samples recorded as being split in moist or wet state. o The main protocol to ensure the RC samples were representative of the material being collected was monitoring of sample recovery and collection and assay of replicate samples. - DD – Primary sample <ul style="list-style-type: none"> o DD cores are collected of intervals determined by geological boundaries but generally targeting a 1m length o All NQ cores have been half-core sampled with the core cut longitudinally with a wet diamond blade. o A small amount of DD whole cores have been sampled from HQ3 cores drilled to twin RC holes in the regolith or for geotechnical or metallurgical testing. o In 2005, some 1,150m of cores drilled in the oxide zone were chisel split rather than wet cut but this poorer sub-sampling represents <0.01% of the core drilled. - Laboratory preparation <ul style="list-style-type: none"> o Sample preparation has taken place at three laboratories since commencement of Mineral Resource definition drilling including SGS Perth (pre- 2006), Genalysis Perth (2006 to April 2016) and Tropicana site laboratory (2015 Boston Shaker samples and post-April 2016 samples) o RC samples were over dried then pulped in a mixer mill to a PSD of 90% passing 75 microns before sub-sampling for fire assay. o SGS prepared DD half-core samples by jaw-crushing then pulverisation of the whole crushed lot to a particle size distribution (PSD) of 90% passing 75 microns. A 50g subsample of the pulp was then collected for fire assay. o Genalysis prepared the samples in a Boyd crusher rotary splitter combo with nominally 2.5kg half-core lots crushed to <3 mm then rotary split to \approx 1 kg before pulverisation and sub-sampling for fire assay. o Samples less with mass <800g submitted to Tropicana laboratory are pulped in a LM2 mill to a PSD of 75 microns before sub-sampling for fire assay. Samples with larger masses are crushed in a Boyd crusher to a PSD of 90% passing 2mm then subsampled using a linear sample divider. o From May 2016, a jaw crusher has been used to crush half-core samples to a PSD of 100% passing 6 mm. - Quality controls for representative sampling: <ul style="list-style-type: none"> o SGS inserted blanks and standards at a 1:20 frequency in every batch with a duplicate pulp collected for assay every 20th sample. Further repeats were also completed at a 1:20 frequency in a random manner. Sieve checks were completed on 5% of samples to monitor PSD compliance.

Criteria	Commentary
	<ul style="list-style-type: none"> o Genalysis inserted blanks and standards in every batch and a duplicate pulp was collected for assay on every 25th sample and 6% of each batch was randomly selected for replicate analysis. Sieve checks were completed on 5% of samples to monitor PSD compliance. o Tropicana laboratory used barren basalt and quartz to clean equipment between routine samples <p>- Sample size versus grain size</p> <ul style="list-style-type: none"> o No specific heterogeneity tests have been carried out but the sample sizes collected are consistent with industry standards for the style of mineralisation under consideration. o A 2008 sampling variability study found that 72% of the gold in the samples tested was in size fraction <300 microns, and that repeated sampling of the same lot have very low variance between replicates.
Quality of assay data and laboratory tests	<ul style="list-style-type: none"> - No geophysical tools were used to determine any element concentrations material to the Mineral Resource estimate. - All Mineral Resource prepared pulps have undergone 50g fire assay which is considered a total assay for gold - As discussed above all laboratories have used industry standard quality control procedures with standards used to monitor accuracy, replicate assay to monitor precision, blanks to monitor potential cross contamination and sieve tests to monitor PSD compliance. - AngloGold has also used other 'umpire' laboratories to monitor accuracy including Genalysis Perth (prior to November 2006), SGS (from November 2006 to August 2007) and ALS Perth (since August 2007), with these check assaying campaigns coinciding with each Mineral Resource update. - AngloGold has reviewed the quality sample results on a batch by batch and monthly basis and has found that the overall performance of the laboratories used for Mineral Resource estimation samples is satisfactory.
Verification of sampling and assaying	<ul style="list-style-type: none"> - Significant intersections of mineralisation are routinely verified by AngloGold senior geological staff and have also been inspected by several independent auditors as describe further below. - Twin holes have been drilled to compare results from RC and DD drilling with the DD results confirming that there is no material down-hole smearing of grades in the nearby RC drilling and sampling. - All logging and sample number data is captured digitally in the field using Field Marshall Software (upgrade to Micromine Geobank in 2016). Data is downloaded daily to the Tropicana exploration server and checked for accuracy, completeness and structure by the field personnel. - Assay data is merged electronically from the laboratories into a central Datashed database, with information verified spatially in Vulcan software. AngloGold maintains standard work procedures for all data management steps. - An assay importing protocol has been set up to ensure quality samples are checked and accepted before data can be loaded into the assay database - All electronic data is routine backed up to AngloGold's server in Perth and provided to IGO via FTP transfer. - There have been no adjustments or scaling of assay data other than setting below detection limit values to half detection for Mineral Resource estimation work.
Location of data points	<ul style="list-style-type: none"> - All early drill hole collar locations of surface holes have been surveyed using RTK GPS equipment, which was connected to the state survey mark (SSM) network. - The grid system is GDA94 Zone 51 using AHD elevation datum. - Prior to 2007, drill hole path surveys have been completed on all holes using Eastman single shot camera tools, with down-hole gyro tools used for all drilling post 2007 - A digital terrain model was prepared Whelan's Surveyors from aerial photography flown in 2007, which has been supplemented with collar data surveyed using RTK GPS. This model is considered to have centimetre-scale accuracy.
Data spacing and distribution	<ul style="list-style-type: none"> - The drill hole spacing nominally ranges from 25mN×25mE to 100mN×100mE (local grid) over most of the Mineral Resource area with a small area of 10mN×10mE used for grade control calibration work. - Most of the Open Pit Mineral Resources has been tested on a 50mN×50mE grid with closer spaced 25mN×25mE patterns in the upper parts of the deposit within initial open pit designs. - The Havana Deeps area has been drilled on a 100mN×100mE pattern. - Down-hole sample intervals are typically 1m with 2m compositing applied for Mineral Resource estimation work. - The Competent Person considers that data spacing is sufficient to establish the degree of geological and grade continuity appropriate for the Mineral Resource and Ore Reserve estimation procedures applied, and the JORC Code classification applied.
Orientation of data in relation to geological structure	<ul style="list-style-type: none"> - Most drill hole are oriented to intersect the shallowly east dipping mineralisation at a high angle and as such, a grade bias introduced by the orientation of data in relation to geological structure is highly unlikely.
Sample security	<ul style="list-style-type: none"> - The chain-of-sample custody is managed by AngloGold.

Criteria	Commentary
	<ul style="list-style-type: none"> - Samples were collected in pre-numbered calico bags, which are then accumulated into calico bags for transport from the collection site. The accumulated samples are then loaded into wooden crates and road hauled to the respective laboratories (Perth or Tropicana). - Sample dispatches are prepared by the field personnel using a database system linked to the drillhole data. - Sample dispatch sheet are verified against samples received at the laboratory and any missing issued such as missing samples and so on are resolved before sample preparation commences. - The Competent Person considers that the likelihood of deliberate or accidental loss, mix-up or contamination of samples is considered very low.
Audits or reviews	<ul style="list-style-type: none"> - Field quality control data and assurance procedures are review on a daily, monthly and quarterly basis by AngloGold field personnel and senior geological staff. - The field quality control and assurance of the sampling was audited by consultant QG in 2007 and 2009. The conclusion of the audit was that the data was suitable for Mineral Resource estimation work.

Section 2 Reporting of Exploration Results

Criteria	Explanation
Mineral tenement and land tenure status	<ul style="list-style-type: none"> - The Tropical Gold Mine Mineral Resources are located wholly within WA mining lease M39/1096, which commenced on 11 Mar 2015 and has a term of 21 years (expiry 10 Mar 2036). - Tropicana Gold Mine in a joint venture between AngloGold (70%) and IGO (30%) with AngloGold as manager. - Gold production is subject to WA State royalties of 2.5% of the value of gold value. - There are no material issues relating to native title or heritage, historical sites, wilderness or national parks, or environmental settings - The tenure is secure at the time of reporting and there are no known impediments to exploitation of the Mineral Resource and Ore Reserve and on-going exploration of the mining lease.
Exploration done by other parties	<ul style="list-style-type: none"> - AngloGold entered in to a JV with IGO in early 2002 with the main target of interest being a WMC gold soil anomaly of 31ppb, which was reporting in a WA government open file report. Prior to the JV, the WMC soil sampling program was the only known exploration activity and the only dataset available were WA government regional magnetic and gravity data.
Geology	<ul style="list-style-type: none"> - The Tropicana Gold Mine is on the western margin of a 700km long magnetic feature that is interpreted to the collision suture zone between the Archean age Yilgarn Craton to the west and the Proterozoic age Albany-Fraser Orogen to the east of this feature. The gold deposits are hosted by a package of Archean age high metamorphic grade gneissic rocks. - Four distinct structural domains have been identified – Boston Shaker, Tropicana, Havana and Havana South, which represent the same mineral deposit offset by NE striking faults that post-date the mineralisation. - The gold mineralisation is hosted by a shallowly SW dipping sequence of quartz-feldspar gneiss, amphibolite, granulite and meta-sedimentary chert. - The gold mineralisation is concentrated in a 'favourable horizon' of quartz-feldspar gneisses, with a footwall of garnet gneiss, amphibolite or granulite. - Mineralisation is characterised by pyrite disseminations, bands and crackle veins within altered quartz-feldspar gneiss. Higher grades are associated with close-spaced veins and sericite alteration - Mineralisation presents as stacked higher grade lenses within a low-grade alteration envelope. Geological studies suggest the mineralisation is related to shear planes that post-date the development of the main gneissic fabric and metamorphic thermal maximum.
Drill hole Information	<ul style="list-style-type: none"> - A summary of the all drillholes used to prepare the Mineral Resource estimate is not practical for this public report. The Mineral Resource estimate gives the best-balanced view of all the drillhole information available as at June, 2017.

Data aggregation methods	- No metal equivalent values are considered in the Mineral Resource estimate.
Relationship between mineralisation widths and intercept lengths	- Exploration results included in this report are for extensional drilling at Boston Shaker (underground resource extension). - All Mineral Resource drilling interests the mineralisation at a high angle and as such approximate true thicknesses in most cases.
Diagrams	- A representative 3d oblique view for Boston Shaker results is included in the body of this report.
Balanced reporting	- The Mineral Resource is based on all available data and as such provides the best-balanced view of the Tropicana gold deposits as at June, 2017. The Exploration results reported are not included in the Mineral Resource Estimate reported.
Other substantive exploration data	- Information relating to other exploration data, such as density, metallurgical assumptions are detailed in Section 3 further below
Further work	- Exploration drilling is continuing at Boston Shaker (Underground resource extension drilling) and will be included in the next Mineral Resource update, planned for Q1, 2018.

Section 3 Estimation and Reporting of Mineral Resources

Criteria	Commentary
Database integrity	- AngloGold captures field data and drill hole logging directly in to handheld devices or laptop computers using Field Marshall and Geobank software. - The drillhole data is managed in DataShed software, which is an industry recognised system for management of geoscientific drillhole information. Logging, assays and survey information is loaded directly into Dashed using data import routines, with loading procedures incorporating quality control checking. - Data is validated following loading through visual inspection of results on-screen both spatially and using database queries and cross section plots. Typical checks carried out against original records to ensure data accuracy include items such as overlapping records, duplicate records, missing intervals, end of drillhole checks and so on.
Site visits	- The Competent Person makes regular site visits to Tropicana to review the data collection procedures and discuss the geology and mineralisation of the deposit prior to any Mineral Resource update.
Geological interpretation	- To control the Mineral Resource estimation process, three dimensional digital solids were prepared in LeapFrog software for the mineralised zones, dykes, shears and garnet (mostly hanging wall) gneiss. - Mineralised solids were prepared using a nominal 0.3g/t AU drill hole cut-off grade to encompass the gold mineralisation targeted for Mineral Resource estimation. The dykes, shears and garnet gneiss solids were prepared from geological logging codes. Regolith units were prepared as digital surfaces below topography based on the geological logging. - The resulting models encompass the mineralisation, the post-mineralisation barren dykes, and the shears controlling higher grade mineralisation and the main waste rock units that are the footwall and hanging wall to the mineralisation.
Dimensions	- The Open Pit Mineral Resource is reported within an open pit Lerchs-Grossman-Analysis (LGA) pit optimisation 'shell' based on a gold price of 1817 AUD/troy ounce (1,400 USD/troy ounce). - This reporting shell has dimensions of approximately 4.7km along strike, up to 1km wide and up to 450m deep, spanning all the major deposits. - The Underground Mineral Resource extends from the base of the Open Pit Resource below the Havana Open Pit with plan extents in long dimension down dip to the SE by up to 900 m and up to ≈200 m wide. A smaller lode extends from the Havana South pit with down dip extents of ≈ 200m and up to 200 m wide. Other parts of the Underground Resource are below the other pits.

Criteria	Commentary
Estimation and modelling techniques	<ul style="list-style-type: none"> - The Open Pit Mineral Resource: <ul style="list-style-type: none"> o Has been estimated from the drillhole data available to 8 Aug 2016, which included 3,381 drill holes for a total of 648,208 m of drilling of which, 981 holes were DD for 351,289 m and 2,256 holes were RC for 259,831 m. A further 144 holes of RC with DD holes totalled 37,087 of drilling. o The December 2016 update included 387 new holes (255 RC and 7 DD) for an additional 99,120m of drilling compared to the prior estimate. o The drillhole data was composited to 2m lengths within geological estimation domains using Vulcan software. o No grade top-cut or caps were applied to the composites, but high-grade estimation limits were applied to limit the spatial spread of high grades. o The composite data was declustered in each estimation domain using cell declustering commensurate with the drill spacing (25mE×25mN or 50mE×50mN and planned kriging panel height (10 m for Havana and Tropicana, 7.5 m for Boston Shaker) o Gold continuity was interpreted for each estimation domain and grades for large panels were estimated using ordinary block kriging in Isatis, with estimation panel dimension 15mE×30mN×10mElv used for Havana and Tropicana, and panels of 15mE×30mN×7.5mElv for Boston Shaker. o Sample searches were oriented down dip with a 160mX×160mY×30mZ search used for mineralised domains and 120mX×120mY×30mZ search in waste domains. A minimum of 8 (or 4 for Boston Shaker) and maximum of 32 samples were required for a panel grade to be estimated. A second pass search was then applied to address blocks not estimated or >1% negative kriging weights with the maximum number of samples reduced to 12. o Selective Mining Unit (SMU) grades were then estimated for each panel using the Local Uniform Conditioning method, where the SMU grade distribution within each panel is estimated through a change of support then the SMUs are localised using kriging so the distribution within the panel reflects the local grade trends in nearby data. The information effect of 12mE×12mN grade control information was accommodated in the change of support from panels to SMUs o The SMU dimensions were set to prepare 36 SMUs per panel with SMU dimensions of 5mE×7.5mN×3.33mElv for Havana and Tropicana and 5mE×7.5mN×2.5mElv for Boston Shaker. The elevation heights nominally match the mining flitch heights applied at each area. o The estimate model was validated by comparing (input) data declustered means for each domain to the respective (output) block estimated grades both globally within each domain and locally using moving window 'swath-plot'. On screen visual inspections were also completed in plan and section to ensure that the grade trends observed in the data were acceptably reproduced in the estimates without over extrapolation in areas of sparse drilling. o Comparison of the Open Pit estimate forecasts to mine production indicates acceptable forecasting performance for monthly, quarterly and annual recompilation periods. - The Underground Mineral Resource: <ul style="list-style-type: none"> o Is estimated in a separate model from the Open Pit with the model oriented to follow the 30° east dip of mineralisation. o The estimate has been prepared using Ordinary Block Kriging in Isatis software into block dimensions 10mX×10mY×2mZ in the rotated coordinates. o Drill hole data were composited to 2m prior to estimation with no-top cuts applied o The model was validated in an equivalent manner to the Open Pit estimates. o There has been no mining of the Underground Resource to compare to the estimate - There are no assumptions relating to deleterious elements of non-grade variables of economic significance. Gold and density are the only relevant variables.
Moisture	<ul style="list-style-type: none"> - The tonnages are estimated on a dry basis.
Cut-off parameters	<ul style="list-style-type: none"> - Open Pit <ul style="list-style-type: none"> o The Open Pit estimate is reported within a pit optimisation run with an assumed gold prices of 1,400 USD/tr.oz (1,817 AUD/tr.oz) and cost assuming back-filling of pits ('Long Island Study'). o On the basis described above, and assuming lower processing costs and higher metallurgical oxide ore, the cut-off are ≥0.3g/t Au for oxide Mineral Resources and ≥0.4g/t Au for transitional and fresh Mineral Resources. - Underground <ul style="list-style-type: none"> o The Underground estimate cut-off grade is based on assumptions of a pre-feasibility study completed in 2013 which used a gold price of 1,400 USD/tr.oz (1,817 AUD/tr.oz) and underground mining and process cost assumptions for fresh Mineral Resource. o The cut-off grade for reporting the Underground Mineral Resource on this basis is ≥2.0g/t Au.
Mining factors or assumptions	<ul style="list-style-type: none"> - The mining factors and assumption for the Open Pit Mineral Resource is the current mining method of conventional truck and shovel mining with blasting of 10 m benches in Tropicana and Havana and blasting of 7.5 m benches in Boston Shaker.

Criteria	Commentary
	<ul style="list-style-type: none"> - Open Pit ore is mined in three 1/3 blast height flitches, with ore predefined by 12mE×12mN RC grade control drilling and 1m downhole sampling. - The assumed Open Pit mining selectivity are the SMU dimensions assumed for the LUC estimates. - The assumption for the Underground Mineral Resource is long-hole open stoping between 20 m levels. - No Mineral Resource margin (external) dilution has been modelled in either estimate. - Eventual prospects of economic extraction for the Open Pit resource have been assessed through pit optimisation studies and reporting the Mineral Resource within pit designs and an optimisation shell. - Eventual prospects of economic extraction for the Underground Resource have been demonstrated in the 2013 study, albeit the project development is not currently economical attractive at current metal prices and costs.
Metallurgical factors or assumptions	<ul style="list-style-type: none"> - The ore processing method at Tropicana is well-established with conventional, crushing, grinding then carbon-in-leach extraction of gold followed by electrowinning to produce gold bars. - An average metallurgical recovery of 90.3% has been assumed for both the Open Pit and Underground Mineral Resources based on metallurgical testing completed as part of the Feasibility Study for the Havana Open Pit.
Environmental factors or assumptions	<ul style="list-style-type: none"> - Tropicana Gold mine operates under an environmental management plan that meets or exceeds all statutory and legislative requirements. - Mined waste rock is disposed in waste dumps which are progressively rehabilitated as mining progresses with any potentially acid generating waste encapsulated in non-acid generating material. - A tailing storage facility is used to contain and capture process residues. - The mine produces rehabilitation plans for ongoing rehabilitation and mine closure plans, and the costs are included in the financial model.
Bulk density	<ul style="list-style-type: none"> - AngloGold routinely collects <i>in situ</i> bulk density measurements on ≈10cm long core segments using the Archimedes principle method of dry weight versus weight in water. There are ≈138,000 density measurements in the estimation database with 131,000 from fresh rock and the remainder in the regolith or cover. - Measurements are collected over 1m to 5 m intervals targeting intervals that are deemed representative of key lithology in fresh rock. Density has been collected on core within the regolith from 'core-from-surface' drill holes, with the measurement method accounting for voids. - Depending on rock type density ranges of 1.89 t/m³ to 2.18 t/m³ in the saprolite and ranges from 2.56 t/m³ to 2.96 t/m³ in the transitional and fresh rock domains. - Density is estimated by ordinary block kriging in the Mineral Resource estimates apart from a few minor domains with sparse data (such as the regolith), where density is assigned as a mean of the data.
Classification	<ul style="list-style-type: none"> - The basis of classification of the Tropicana estimates into different JORC Code confidence categories is drill hole spacing as follows: <ul style="list-style-type: none"> o Measured Mineral Resources: average 25mE×25mN collar spacing. o Indicated Mineral Resources: average 50mE×50mN collar spacing. o Inferred Mineral Resources: average 100mE×100mN collar spacing (or less) when evidence of geological or grade continuity is sufficient to support grade estimation. - AngloGold considers that the Measured Resource supports mine planning with a 90% confidence interval of ±15% on tonnage or grade on a quarterly production basis, with Indicated Resources have the same confidence but applicable on an annual production basis. - The Competent Person considers this classification takes in to account all relevant factors such as data reliability, confidence in the continuity of geology and grades, and the quality, quantity and distribution of the data. - The classification reflects the view of the Competent Person reporting the estimate with the same methodology applied to both the Open Pit and Underground estimates.
Audits or reviews	<ul style="list-style-type: none"> - The Open Pit estimate methodology was audited by consultant QG in 2007, 2009 and 2011. - Consultants Golder Associates audited the 2015 estimate in 2015 with recommendations that have been adopted in the current estimate. - AngloGold conducts internal peer review prior to the release of any Mineral Resource update.
Relative Accuracy/Confidence	<ul style="list-style-type: none"> - AngloGold has carried out some non-conditional simulation studies to confirm the relationship between drill spacing and 90% confidence interval assumptions and found the study results in agreement with the drill spacing classification criteria described above. - The trial grade 10mE×10mN control pattern drilled within an 100m×100m area during the project Feasibility Study has also confirmed the precision assumptions and confidence the Mineral Resource estimate in that area - Mine reconciliation for the life-of-mine to date is satisfactory.

Section 4 Estimation and Reporting of Ore Reserves

Criteria	Commentary
Mineral Resource estimate for conversion to Ore Reserves	<ul style="list-style-type: none"> - The estimate used for the Ore Reserve study is the Open Pit estimate described in the preceding sections of this JORC table 1. - The Tropicana Open Pit Mineral Resource is reported inclusive of the Ore Reserve. - No Ore Reserve has been estimated from the Underground Mineral Resource estimate.
Site visits	<ul style="list-style-type: none"> - The Competent Person for the Ore Reserve is the Senior LoM Planning Engineer and as such has intimate knowledge of the operation and is in daily contact when on site with personnel providing key inputs to the estimate.
Study status	<ul style="list-style-type: none"> - The level of study for the Ore Reserve estimate is commensurate with industry expectations of a Feasibility Study as described in the JORC Code, with all material Modifying Factors considered in the Ore Reserve estimate. - Current mining and processing operations confirming that the mine plans are technically feasible and economically viable
Cut-off parameters	<ul style="list-style-type: none"> - The Ore Reserve reporting cut-offs are determined based on the net return of gold produced at the processing plant for each ore type. - The specific cut-offs for reporting the Ore Reserve are; $\geq 0.6\text{g/t Au}$ for oxide and $\geq 0.7\text{ g/t Au}$ for transitional and fresh rock.
Mining factors or assumptions	<ul style="list-style-type: none"> - The mining method for the Ore Reserve is open pit mining with conventional excavators and trucks with blasting on 10m benches in Tropicana and Havana and 7.5 m in Boston Shaker. Ore is mined in three 1/3 bench height flitches. - Inter-ramp pit slope angles are assumed to be 35° on the footwall and 67° on the hangingwall in both oxide and fresh rock, modified depending on lithology and alteration type. - The Ore Reserve is reported within operation designs that have been prepared using the Mineral Resource model described above, geotechnical inputs and financial assumptions discussed below. - Grade control RC drilling is completed on a $12\text{mE}\times 12\text{mN}$ pattern prior to ore mining. - No mining dilution has been applied as the LUC model incorporates internal dilution. - Mining recovery of ore is assumed to be 100% - Mine designs assume a minimum working face of 50m to 80 m at the base of pits. - Inferred Mineral Resources are excluded from the Ore Reserve with the total in-pit Inferred Resource being $<0.001\%$ of the Ore reserve and as such, is no material to the mine viability. - No new infrastructure is required to support the operating mine methods.
Metallurgical factors or assumptions	<ul style="list-style-type: none"> - The metallurgical process for Tropicana ores is already established and is a process flow of crushing (grinding rolls), grinding the recovery of gold through carbon-in-leach and electrowinning to produce gold bars. - Gold recovery factors are based on extensive metallurgical testing and range from 92.5% recovery in mineralised transported material down to 89.9% recovery in fresh rock. - No deleterious elements are present in the ore. - In the project Feasibility Study Pilot scale test work was carried out on large diameter (PQ) core collected in a spatially representative manner from the deposit. To date metallurgical recoveries have been consistent with the forecasts from these studies. - As a gold mine, the gold doré bars produced are not subject to any specification requirements.
Environmental	<ul style="list-style-type: none"> - Tropicana Gold mine operates under an environmental manage plant that meets or exceeds all statutory and legislative requirements. - Miner rock wastes are disposed in waste dumps which are progressively rehabilitated as mining progresses with any potentially acid generating waste encapsulated in non-acid generating material. - A tailing storage facility is used to contain and capture process residues. - The mine produces rehabilitation plans for ongoing rehabilitation and mine closure plans, and the costs are included in the financial model.
Infrastructure	<ul style="list-style-type: none"> - All major infrastructure required for the mining and processing is in place. - The owner and contractor staffing is fully complete, with personnel sourced on a fly-in-out basis from Perth or Kalgoorlie. - No other significant infrastructure is anticipated and sustaining capital cost for infrastructure are included in the financial model.
Costs	<ul style="list-style-type: none"> - The capital cost of removing waste overburden are included in the evaluation of the applicable pit designs. - Mining operating costs are provided by the mining contractor and other costs are sourced from in the mine operating budget. - As discussed there are no deleterious elements and as such related costs are not relevant - The source of AUD:USD exchange rates is AngloGold/IGO corporate guidance

Criteria	Commentary
	<ul style="list-style-type: none"> - Transpiration charges for gold doré bars is relatively minor and are charged on a contract basis with the refinery. - Treatment and refining charges are included in the refining contract and there are no specification ore penalties associated with treatment and refining. - WA State royalties are levied at 2.5% of the value of gold produced.
Revenue factors	<ul style="list-style-type: none"> - The assumption for gold prices for the Ore Reserve is 1,100 USD/tr.oz based on corporate guidance and assessment of historical prices - The AUD:USE exchange rate is 0.74, also based on corporate guidance and assessment of historical exchange rates.
Market assessment	<ul style="list-style-type: none"> - No specific market assessment has been completed for this Ore Reserve update.
Economic	<ul style="list-style-type: none"> - The inputs into the economic analysis for the Ore Reserve update have already been described above under previous subsections. - The economic evaluation has been carried out on a real basis (adjusted for inflation) with rates provided by AngloGold corporate. - The confidence in majority of the economic inputs is high as Tropicana is an operating mine and as such, costs (opex and capex) are well understood. - The confidence in metal prices and exchange rates is consistent with routine industry practices with the data derived from reputable forecasters. - The discount rate used for NPV calculations is derived from the weighted average cost of capital in Australia. - Sensitivity studies have been completed on inputs such a mining and processing costs, gold price and discount rate. NPV has the greatest sensitivity to gold price with an estimated 30,000 ounces lost from the Ore Reserve for a 10% reduction in gold price.
Social	<ul style="list-style-type: none"> - Tropicana Gold Mine has all necessary agreements in place with key stakeholders and matters leading to social licence to operate.
Other	<ul style="list-style-type: none"> - There are no material naturally occurring risks associated with the Tropicana operation. - There are no material legal agreements or marketing arrangements not already discussed in prior sub sections. - All necessary government and statutory approvals are in place. - There are no unresolved third-party matters hindering the extraction of the Ore Reserve.
Classification	<ul style="list-style-type: none"> - The Ore Reserve has been classified into Proved and Probable Ore Reserve JORC Code classes based on the underlying MRE classification in the MRE model, with Measured Mineral Resources converted to Proven Ore Reserves, and Indicated Mineral Resources converted to Probable Ore Reserves. - The classifications applied to the estimate are consistent with the opinion of the Competent Person reporting the Ore Reserve. - There is no portion of Probable Ore Reserves derived from Measured Mineral Resources
Audits or reviews	<ul style="list-style-type: none"> - A Mineral Resource and Ore Reserve audit was completed in 2017 and no material recommendation came from the audit - The current Ore Reserve estimate has been reviewed internally by AngloGold personnel
Discussion of relative accuracy/ confidence	<ul style="list-style-type: none"> - AngloGold has carried out simulation to quantify the confidence in the Ore reserve – refer to the commentary at the end of Section 3 above. - The main driver of accuracy and confidence is the spacing of the pre-production drilling, which is captured in the Mineral Resource JORC Code classifications underpinning the Ore Reserve estimates. - Confidence in Ore Reserve inputs is generally high given the mine is operation and costs, prices, recoveries and so on are well understood. - The Ore Reserve estimates are considerate to have sufficient local accuracy to support mine planning and production schedules with Proved Ore Reserves considered a reliable basis for quarterly production targeting and Probable Ore Reserves reliable for annual production targets. - Confidence in the mine design and schedule are high as mining rates and modifying factors are based on actual site performance. Mine designs are consistent with what has been effective previously. - The mine to mill reconciliation data to date indicates the forecast precision of the estimates is good with the Ore Reserve estimate slightly conservative.
